10  $n$  is 0 to 3; and  
 $p$  is 0 to 3.

In the above definitions, the term "alkyl", used either alone or in compound words such as "alkylthio" or  
15 "haloalkyl", means straight chain or branched alkyl such as methyl, ethyl, n-propyl, isopropyl or the different butyl, pentyl, hexyl isomers.

Alkoxy includes methoxy, ethoxy, n-propyloxy, isopropyloxy and the different butoxy or pentoxy isomers.

20 Alkenyl includes straight chain or branched alkenes, such as vinyl, 1-propenyl, 2-propenyl, 3-propenyl and the different butenyl, pentenyl and hexenyl isomers.

Alkynyl includes straight chain or branched  
25 alkynes, such as ethynyl, 1-propynyl, 2-propynyl and the different butynyl, pentynyl and hexynyl isomers.

Alkylthio includes methylthio, ethylthio and the different propylthio and butylthio isomers.

Alkylsulfonyl and the like are used analogously to  
30 the above examples.

Cycloalkyl includes cyclopropyl, cyclobutyl, cyclopentyl and cyclohexyl.

The term "halogen", either alone or in compound words such as "haloalkyl", means fluorine, chlorine,  
35 bromine or iodine. Further, when used in compound words

such as "haloalkyl" said alkyl can be partially or fully substituted with halogen atoms, which may be the same or different. Examples of haloalkyl include  $\text{CH}_2\text{CH}_2\text{F}$ ,  $\text{CF}_2\text{CF}_2\text{H}$  and  $\text{CH}_2\text{CHFCl}$ . The terms "halocycloalkyl", "haloalkenyl" and "haloalkynyl" are used analogously to "haloalkyl".

The total number of carbon atoms in a substituent group is indicated by the " $\text{C}_i$  to  $\text{C}_j$ " prefix where  $i$  and  $j$  are numbers from 1 to 8. For example,  $\text{C}_1$  to  $\text{C}_3$  alkylsulfonyl would designate methylsulfonyl through propylsulfonyl;  $\text{C}_2$  alkoxyalkoxy would designate  $\text{OCH}_2\text{OCH}_3$ ;  $\text{C}_4$  alkoxyalkoxy would designate the various isomers of an alkoxy group substituted with a second alkoxy group containing a total of 4 carbon atoms, examples including  $\text{OCH}_2\text{OCH}_2\text{CH}_2\text{CH}_3$  and  $\text{OCH}_2\text{CH}_2\text{OCH}_2\text{CH}_3$ ;  $\text{C}_2$  cyanoalkyl would designate  $\text{CH}_2\text{CN}$  and  $\text{C}_3$  cyanoalkyl would designate  $\text{CH}_2\text{CH}_2\text{CN}$  and  $\text{CH}(\text{CN})\text{CH}_3$ ;  $\text{C}_2$  alkylcarbonyl would designate  $\text{C}(\text{O})\text{CH}_3$  and  $\text{C}_4$  alkylcarbonyl would include  $\text{C}(\text{O})\text{CH}_2\text{CH}_2\text{CH}_3$  and  $\text{C}(\text{O})\text{CH}(\text{CH}_3)_2$ ; and as a final example,  $\text{C}_3$  alkoxycarbonylalkyl would designate  $\text{CH}_2\text{CO}_2\text{CH}_3$  and  $\text{C}_4$  alkoxycarbonylalkyl would include  $\text{CH}_2\text{CH}_2\text{CO}_2\text{CH}_3$ ,  $\text{CH}_2\text{CO}_2\text{CH}_2\text{CH}_3$  and  $\text{CH}(\text{CH}_3)\text{CO}_2\text{CH}_3$ .

Details of the Invention

Compounds of Formula I can be obtained by the reaction of activated carbonyl or thiocarbonyl compounds of Formula II with substituted anilines in the presence or absence of an acid acceptor or suitable condensing agent. Methods for performing this transformation are well known in the art; see, Zabicky, "The Chemistry of the Amides", Interscience, 1970.

One particularly useful method involves the chlorination of an acid derivative (II,  $X_1 = OH$ ) with thionyl chloride or another chlorinating agent followed by treatment with an aniline (III) in the presence of an acid acceptor such as an amine base, preferably triethylamine. Suitable solvents for the chlorination reaction are inert to hydrogen chloride and include benzene, toluene, and dichloromethane. Preferred temperatures for this process are from 20° to 100°C with temperatures between 20° and 80°C being particularly preferred. The latter reaction can be carried out in many different inert solvents such as dialkylethers, chlorinated hydrocarbons, and aromatic hydrocarbons. While temperatures at or below 25°C are preferred, higher temperatures can also be employed. These reactions are normally run at atmospheric pressure, but can also be carried out at elevated pressures.

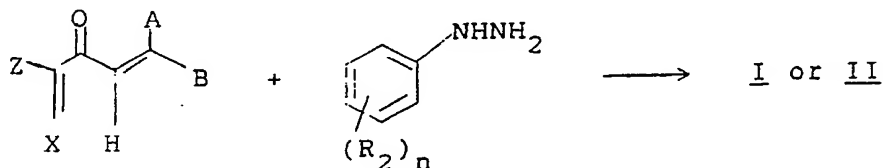

Esters of Formula II ( $X_1 = C_1$  to  $C_6$  alkoxy)  
5 can be converted directly to compounds of Formula I in several ways. In the presence of Lewis acids such as  $AlMe_3$ , anilines react readily with esters of Formula II. The reaction is best carried out at room temperature to 120°C. Suitable solvents include  
10 dichloromethane, 1,2-dichloroethane, and toluene. The method described by Weinreb et al., Organic Synthesis, 59, 49, (1982), proceeds best with esters of lower alcohols such as methanol or ethanol.

Acids of Formula II ( $X_1 = OH$ ) can be converted  
15 directly to compounds of Formula I by use of coupling agents known in the peptide art in conjunction with anilines. Coupling agents include dicyclohexylcarbodiimide (DCC), N-hydroxysuccinimide, 2-chloro-N-methylpyridinium iodide, carbonyl diimidazole, or  
20 other agents capable of activating an acid function or acting as a dehydrating agent. These and other methods are described in Gross et al., "The Peptides," 3 Vols., Academic Press, New York, 1979 to 1981.

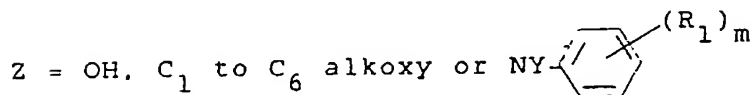

Compounds of Formula I can also be obtained from  
25 the cyclization of appropriate phenylhydrazines (V) with keto-acid derivatives (IV). It will be appreciated by those skilled in the art that this process applies equally to acids, esters, and anilides and further that the interconversion of these groups as  
30 discussed in the sequence (II→I) can be carried out after the cyclization reaction. The conditions for these reactions are well known in the art and described by Hill et al., Trans. Illinois Acad. Sci., 33 (1940), 112 and by Vaughan, J. Org. Chem., 20 (1955), 1619.  
35 The cyclization reaction is best carried out on an unsaturated keto-acid derivative (IV) in refluxing alcoholic media, in refluxing lower carboxylic

acids, or in polar aprotic solvents such as  
 5 dimethylformamide or dimethyl sulfoxide. Ethanol  
 containing acetic acid or acetic acid alone are the  
 preferred solvents although other protic or aprotic  
 solvents and mixtures are also applicable. In some  
 cases, phenyl hydrazones can be isolated prior to final  
 10 cyclization and these can be refluxed further in order  
 to complete the cyclization. While the unsaturated  
 acid derivatives (IV) are preferred, saturated com-  
 pounds with a reactive group such as a halogen beta to  
 the carbonyl can be employed in certain instances.

Compounds of Formula I and intermediates of  
 Formula II can also be obtained by the dipolar cyclo-  
 addition reaction of nitrile-imines, generated from  
 substituted phenylhydrazones of Formula VI, with  
 appropriately substituted alkenes. The presence of an  
 30 acid acceptor (generally an amine base, for example,  
 triethylamine) is necessary for the formation of the  
 nitrile-imine. In a typical reaction, the alkene is  
 used in a two- to five-fold molar excess and the amine  
 base in a three- to five-fold excess based on the  
 35 hydrazone (VI). Suitable solvents include but are not  
 restricted to benzene, toluene, 1,2-dichloro-  
 ethane, chloroform, and tetrahydrofuran. The reaction  
 can be carried out at temperatures ranging from 20° to  
 120°C with the relative reactivity of the alkene (VII)  
 governing the required temperature for a given example.

The required hydrazones (VI) for the synthesis of compounds of Formula I and II can be prepared by methods known in the art or by modifications thereof; see, e.g., Shawali et al., Tetrahedron, 20 (1971), 2517.

Some compounds of Formula I (Y=H) can be converted to other compounds of Formula I by alkylation, acylation, and sulphenylation reactions (Y=H). Reaction of compounds of Formula I in the presence of an acid acceptor with electrophilic agents (Y-leaving group) results in substitution on nitrogen. Strong bases such as sodium hydride, potassium t-butoxide, potassium hydride, and other bases known in the art to deprotonate amides are preferred in the process. Suitable electrophiles include, but are not restricted to alkyl halides, acyl halides, acid anhydrides, carbonates, chloroformates, disulphides, and sulphenyl halides. This reaction is normally run in the temperature range of 0-25°C, but can be run at temperatures up to 120°C if unreactive electrophiles are used. Solvents not deprotonated

15

under the reactions conditions such as tetrahydrofuran, dimethylformamide, dimethoxyethane, and diethyl ether are preferred.

Compounds of Formula I (X=O) can be converted to  
5 compounds of Formula I (X=S) by means of thiating agents. Conversion of amides to thioamides is well known in the art. Phosphorous pentasulfide either alone or in combination with organic or inorganic  
10 bases is a preferred reagent to effect this conversion. When phosphorous pentasulfide is used alone, organic bases such as pyridine are the preferred solvents. When it is used in conjunction with inorganic bases such as sodium bicarbonate, the preferred solvents are ethers such as diglyme.  
15 Temperatures between 20° to 160°C can be employed successfully with temperatures between 90° to 120°C preferred. These and other means to convert amides to thioamides are described by Lapucha, Synthesis (1987), 256.

20 It will be appreciated by those skilled in the art that, regardless of the method of synthesis, compounds of Formula II can be converted to compounds of the instant invention by the methods described above. Many functional group transformations known to those  
25 skilled in the art can be employed to convert compounds of Formula I to new compounds of Formula I and that this will overcome any incompatibility of certain such groups with reagents and conditions disclosed above with respect to typical reaction  
30 mechanisms.

Formulation and Use

The compounds of this invention will generally be used in formulation with a carrier comprising a liquid or solid diluent or an organic solvent. Useful formulations of the compounds of Formula I can be prepared in conventional ways. They include dusts, granules, pellets, solutions, suspensions, emulsions, wettable powders, emulsifiable concentrates, dry flowables and the like. Many of these can be applied directly. Sprayable formulations can be extended in suitable media and used at spray volumes of from about one to several hundred liters per hectare. High strength compositions are primarily used as intermediates for further formulation. The formulations, broadly, contain about 1% to 99% by weight of active ingredient(s) and at least one of a) about 0.1% to 20% surfactant(s) and b) about 5% to 99% solid or liquid diluent(s). More specifically, they will contain these ingredients in the following approximate proportions:

		<u>Percent by Weight</u>		
		<u>Active</u>	<u>Diluent(s)</u>	<u>Surfactant(s)</u>
		<u>Ingredient</u>		
	Wettable Powders	25-90	0-74	1-10
25	Oil Suspensions, Emulsions, Solutions, (including Emulsifiable Concentrates)	1-50	40-95	0-35
	Dusts	1-25	70-99	0-5
	Granules and Pellets	1-95	5-99	0-15
30	High Strength Compositions	90-99	0-10	0-2

Lower or higher levels of active ingredient can, of course, be present depending on the intended use and the physical properties of the compound. Higher ratios of surfactant to active ingredient are some-

times desirable, and are achieved by incorporation into the formulation or by tank mixing.

Typical solid diluents are described in Watkins, et al., "Handbook of Insecticide Dust Diluents and Carriers", 2nd Ed., Dorland Books, Caldwell, New Jersey. The more absorptive diluents are preferred for wettable powders and the denser ones for dusts. Typical liquid diluents and solvents are described in Marsden, "Solvents Guide," 2nd Ed., Interscience, New York, 1950. Solubility under 0.1% is preferred for suspension concentrates; solution concentrates are preferably stable against phase separation at 0°C. "McCutcheon's Detergents and Emulsifiers Annual", Allured Publ. Corp., Ridgewood, New Jersey, as well as Sisely and Wood, "Encyclopedia of Surface Active Agents", Chemical Publ. Co., Inc., New York, 1964, list surfactants and recommended uses. All formulations can contain minor amounts of additives to reduce foam, caking, corrosion, microbiological growth, etc. Preferably, ingredients should be approved by the U.S. Environmental Protection Agency for the use intended.

The methods of making such compositions are well known. Solutions are prepared by simply mixing the ingredients. Fine solid compositions are made by blending and, usually, grinding as in a hammer or fluid energy mill. Suspensions are prepared by wet milling (see, for example, U.S. 3,060,084). Granules and pellets can be made by spraying the active material upon preformed granular carriers or by agglomeration techniques. See Browning, "Agglomeration", Chemical Engineering, December 4, 1967, pages 147 and following, and "Perry's Chemical Engineer's Handbook", 4th Ed., McGraw-Hill, New York, 1963, pages 8 to 59 and following.

Many of the compounds of the invention are most efficacious when applied in the form of an emulsifiable concentrate mixed with a spray oil or spray oil concentrate. Although any oil can be used as a spray oil, spray oils usually have these characteristics: they are not phytotoxic to the crop sprayed, and they have appropriate viscosity. Petroleum based oils are commonly used for spraying. In some areas, crop oils are preferred such as the following:

Common Crop Oils Used as Spray Oils

	Corn Oil	Linseed Oil
	Cottonseed Oil	Soybean Oil
	Coconut Oil	Sunflower Oil
	Rapeseed Oil	Olive Oil
15	Peanut Oil	Palm Oil
	Safflower Oil	Sesame Oil
	Mustardseed Oil	Caster Oil

The following oils also meet the criteria for a spray oil: mineral, fish and cod liver oil.

Spray oil concentrates comprise a spray oil together with one or more additional ingredients such as emulsifiers and wetting agents. A number of useful spray oil and spray oil concentrates can be found in "A Guide to Agricultural Spray Adjuvants Used in the United States" by Thomson, Thomson Publications, California, 1986.

Examples of useful formulations of compounds of the present invention are as follows:

Example 23

Emulsifiable Concentrate

	N,5-bis(4-chlorophenyl)-1-(4-fluorophenyl)-4,5-dihydro-1H-pyrazole-3-carboxamide	20%
	blend of oil soluble sulfonates and polyoxyethylene ethers	10%
35	isophorone	70%

101

The ingredients are combined and stirred with gentle warming to speed solution. A fine screen filter is included in packaging operation to insure the absence of any extraneous undissolved material in the product.

Example 24Wettable Powder

10 Methyl 1-(4-chlorophenyl)-4,5-dihydro-5-methyl-3-  
[[4-(trifluoromethyl)phenyl]aminocarbonyl]-1H-  
pyrazole-5-carboxylate 30%  
sodium alkylnaphthalenesulfonate 2%  
sodium ligninsulfonate 2%  
15 synthetic amorphous silica 3%  
kaolinite 63%

The active ingredient is mixed with the inert materials in a blender. After grinding in a hammer-mill, the material is re-blended and sifted through a 50 mesh screen.

Example 25Dust

Wettable powder of Example 24 10%  
pyrophyllite (powder) 90%

25 The wettable powder and the pyrophyllite diluent are thoroughly blended and then packaged. The product is suitable for use as a dust.

Example 26Granule

30 1,5-bis(4-chlorophenyl)-4,5-dihydro-N-[4-(trifluoro-  
methyl)phenyl]-1H-pyrazole-3-carboxamide 10%  
attapulgitite granules (low volatile  
matter, 0.71/0.30 mm; U.S.S. No.  
25-50 sieves) 90%

35 The active ingredient is dissolved in a volatile solvent such as acetone and sprayed upon dedusted and pre-warmed attapulgitite granules in a double cone blender. The acetone is then driven off by heating. The granules are then allowed to cool and are packaged.

### Example 27

Granule

5	Wettable powder of Example 24	15%
	gypsum	69%

The ingredients are blended in a rotating mixer and water sprayed on to accomplish granulation. When most of the material has reached the desired range of 0.1 to 0.42 mm (U.S.S. No. 18 to 40 sieves), the granules are removed, dried, and screened. Oversize material is crushed to produce additional material in the desired range. These granules contain 4.5% active ingredient.

### Example 28

### Solution

N,5-bis(4-chlorophenyl)-1-(4-fluorophenyl)-4,5-dihydro-1H-pyrazole-3-carboxamide	25%
N-methyl-pyrrolidone	75%

The ingredients are combined and stirred to produce a solution suitable for direct, low volume application.

- 30 Utility

The compounds of the present invention exhibit activity against a wide spectrum of foliar and soil inhabiting insects. Those skilled in the art will recognize that not all compounds are equally effective against all insects, but the compounds of this invention display activity against economically

important pest species, such as grasshoppers and  
cockroaches; thrips; hemipterans: plant bugs  
5 (Miridae), such as tarnished plant bug, lace bugs  
(Tingidae), seed bugs (Lygaeidae) such as cinch bugs,  
stink bugs (Pentatomidae), leaf-footed bugs  
(Coreidae), such as squash bug, and red bugs and  
stainers (Pyrrhocoridae) such as cotton stainer; also  
10 homopterans such as whiteflies, leafhoppers,  
spittlebugs and planthoppers such as aster leafhopper,  
potato leafhopper and rice planthoppers, psyllids such  
as pear psylla, scales (coccids and diaspidids) and  
mealybugs; coleopterans including weevils, such as  
15 boll weevil and rice water weevil, grain borers,  
chrysomellid beetles, such as Colorado potato beetle,  
flea beetles and other leaf beetles, coccinellid  
beetles such as Mexican bean beetle, and soil insects  
such as southern corn rootworm and wireworm;  
20 lepidopterous larvae including noctuids such as fall  
armyworm, beet armyworm, other Spodoptera spp.,  
Heliothis virescens, Heliothis zea, cabbage looper,  
green cloverworm, velvetbean caterpillar, cotton  
leafworm, black cutworm, and other noctuid cutworms  
25 and including pyralids such as European corn borer,  
navel orangeworm, and stalk/stem borers and including  
tortricids like codling moth and grape berry moth as  
well as pink bollworm and diamondback moth; and  
dipterans such as leafminers, soil maggots, midges,  
30 tephritid fruit flies. The specific species, for  
which control is exemplified below, are: fall  
armyworm, Spodoptera frugiperda; tobacco budworm,  
Heliothis virescens; boll weevil, Anthonomus grandis;  
European corn borer, Ostrinia nubilalis; southern corn  
35 rootworm, Diabrotica undecimpunctata howardi; and

aster leafhopper, Macrosteles fascifrons. The pest control afforded by the compounds of the present invention is not limited, however, to these species.

Application

Insects are controlled and agricultural crops are protected by applying one or more of the Formula I compounds of this invention, in an effective amount, to the locus of infestation, to the area to be protected, or directly on the pests to be controlled. A preferred method of application is by spraying with spray equipment that distributes the compound on the foliage, in the soil, or to the plant part that is infested or needs to be protected. Alternatively, granular formulations of these compounds can be applied to soil or foliage or, optionally, incorporated into the soil. Either aerial or ground application can be used.

The pyrazoline compound(s) of this invention can be applied directly, but most often application will be of a formulation comprising one or more compounds of this invention, in an agriculturally suitable carrier or diluent. A most preferred method of application involves spraying a water dispersion or refined oil solution of the compounds. Combinations with spray oils and spray oil concentrates often enhance the efficacy of the compounds of Formula I.

The rate of application of the Formula I compounds required for effective control will depend on such factors as the species of insect to be controlled, the pest's life stage, its size, its location, the host crop, time of year of application, ambient moisture, temperature conditions, and the like. In general, application rates of 0.05 to 2 kg

of active ingredient per hectare are sufficient to provide effective control in large scale field operations under normal circumstances, but as little as 0.01 kg/hectare may be sufficient or as much as 8 kg/hectare may be required, depending upon the factors listed above. The addition of a compound such as piperonyl butoxide, can enhance the insecticidal activity of the compounds of Formula I.

The following Examples demonstrate the control efficacy of compounds of Formula I on specific insect pests wherein Compounds 1 through 476 and Compounds 1A through 132A are described in Tables 6 and 7, respectively.

Example 32Fall Armyworm

5        Test units, each consisting of an 8-ounce plastic cup containing a layer of wheat germ diet, approximately 0.5 cm thick, were prepared. Ten third-instar larvae of fall armyworm (Spodoptera frugiperda) were placed into each cup. Solutions of each of the test compounds (acetone/distilled water 75/25 solvent) were  
10        sprayed onto the cups, a single solution per set of three cups. Spraying was accomplished by passing the cups, on a conveyer belt, directly beneath a flat fan hydraulic nozzle which discharged the spray at a rate  
15        of 0.5 pounds of active ingredient per acre (about 0.55 kg/ha) at 30 p.s.i. The cups were then covered and held at 27°C and 50% relative humidity for 72 hours, after which time mortality readings were taken.

Example 38Combinations with Spray Oils

5           Both short-term and residual insecticidal  
activity of the tested compound (Compound 30) against  
fall armyworm, Spodoptera frugiperda, was improved  
when the emulsifiable concentrate formulation of the  
compound was combined with spray oils or spray oil  
10 concentrates.

The test compound was diluted in 5 ml of acetone  
and then mixed with distilled water to 100 and 50  
ppm. Spray oil or spray oil concentrate was added to  
the solutions in the ratio 10:1 oil:active  
15 ingredient. The spray oil was a paraffinic  
petroleum-based oil having a median distillation  
temperature at atmospheric pressure of 377°C. The  
spray oil concentrate consisted of 83% isoparaffinic  
oil and 17% of a mixture of sorbitol ester and  
20 epoxylated sorbitol ester. Test units consisted of 3  
week-old soybean plants growing in 4 inch pots. Three  
plants were sprayed to runoff on a turntable sprayer  
at 10 rpm with an atomizing nozzle for each treatment.

After the spray dried, treated leaflets were cut  
25 in half and each piece was placed in one well of a  
6-cell tissue culture plate. One third instar larva  
was placed in each cell. The entire unit was then  
capped with a piece of moistened blotter paper. Four  
such units were set up for each treatment. Test units  
30 were held at 27°C and 50% relative humidity.  
Mortality was assessed at 72 hours. Treated plants  
were held at 27°C and 50% relative humidity and the  
test was repeated at 7 and 14 days to determine  
residual activity.

Example 39Improved Activity with Synergists

Test units were prepared as described in Example 32 using 5 fall armyworm larvae, Spodoptera frugiperda. Prior to treatment with the test compound (Compound 30), the units were oversprayed with the piperonyl butoxide (PBO) at a rate 5X the concentration to be used for the test compound, using the technique described in Example 32. After 2.5 hours, the units were oversprayed with the test compound at 10, 5, 2.5, 1.0, 0.5 and 0.1 ppm. The test units were covered and held for 72 hours at 27°C and 50% relative humidity after which time mortality was assessed. The results are recorded in Table 9.
